

# GIT & GITHUB

## Basics of Distributed Version Control

*(some slides courtesy of Pro Git)*

# Overview

0. What is Git? Installation and setup
1. Introduction to version control; basic workflow in Git
2. Branching, merging, and rebasing
3. Working with remotes and Github

# What is Git?

- A *distributed* version control system
- A few use cases:
  - ▣ Keep a history of previous versions
  - ▣ Develop simultaneously on different branches
    - Easily try out new features, integrate them into production or throw them out
  - ▣ Collaborate with other developers
    - “Push” and “pull” code from hosted repositories such as Github

# Key improvements

- A *distributed* version control system
  - ▣ Everyone can act as the “server”
  - ▣ Everyone mirrors the entire repository instead of simply checking out the latest version of the code (unlike svn)
- Many local operations
  - ▣ Cheap to create new branches, merge, etc.
  - ▣ Speed increases over non-distributed systems like svn

# Installation and setup

---

- ❑ <http://git-scm.com/download> (try this first)
- ❑ Linux: apt-get install git-core
- ❑ Mac: <http://code.google.com/p/git-osx-installer/>
- ❑ Windows: <http://msysgit.github.com/>
  - Git bash
- ❑ Eclipse extensions such as eGit
- ❑ Github GUI

# First time setup

- ❑ `git config --global user.name "Name surname"`
- ❑ `git config --global user.email "name@mit.edu"`
  - ▣ This email should be registered in your Github (more on this later)
- ❑ Line breaks (`\r\n` in Windows vs. `\n` in Mac/Linux)
  - ▣ Mac/Linux: `git config --global core.autocrlf input`
  - ▣ Windows: `git config --global core.autocrlf true`

## Use case #1: history of versions

- ❑ Basic workflow
- ❑ Adding and committing files
- ❑ The git log
- ❑ The staging area
- ❑ Removing files
- ❑ Viewing diffs of files
- ❑ The .gitignore file

# Big ideas

- Snapshots, not deltas
- Everything is confined to the .git directory
- Most operations are safe – they only add data
  - ▣ We'll talk about two commands that are not safe today
- 3 possible states for a file
  - ▣ Changed
  - ▣ Staged
  - ▣ Committed

# Basic workflow

- **git init** – create git project in existing directory
  - ▣ Make Git start to “watch” for changes in the directory
- The basic workflow:

# Basic workflow

---

- Add files to be committed with **git add <filename>**
  - ▣ Puts the file in the “staging area”
- Create a commit (a “snapshot”) of added files with **git commit**, followed by a commit message
- Use **git status** to see the current status of your working tree

# The git status output

```
cliu:git charlesliu$ git status
# On branch master
# Changes to be committed:
#   (use "git reset HEAD <file>..." to unstage)
#
#       new file:   b
#
# Changed but not updated:
#   (use "git add <file>..." to update what will be committed)
#   (use "git checkout -- <file>..." to discard changes in working directory)
#
#       modified:   a
#
# Untracked files:
#   (use "git add <file>..." to include in what will be committed)
#
#       c
```

# The git log output

```
cliu:git charlesliu$ git log
commit d2fb80a79c3188da6fdf1f5b578dde68603feed0
Author: Charles Liu <cliu2014@mit.edu>
Date:   Tue Jan 8 01:37:15 2013 -0500

    Commit #2

    You can enter a longer commit message here. Try to keep the first line short

commit 336993e77c782190506c00c0857e757460f45c76
Author: Charles Liu <cliu2014@mit.edu>
Date:   Tue Jan 8 01:29:14 2013 -0500

    initial commit
^END^
```

# The staging area

- git add takes the snapshot of the file that will be committed → you can change the file after adding it

```
cliu:git charlesliu$ git status
# On branch master
# Changes to be committed:
#   (use "git reset HEAD <file>..." to unstage)
#
#       new file:   c
#
# Changed but not updated:
#   (use "git add <file>..." to update what will be committed)
#   (use "git checkout -- <file>..." to discard changes in working directory)
#
#       modified:   c
#
```

# The staging area

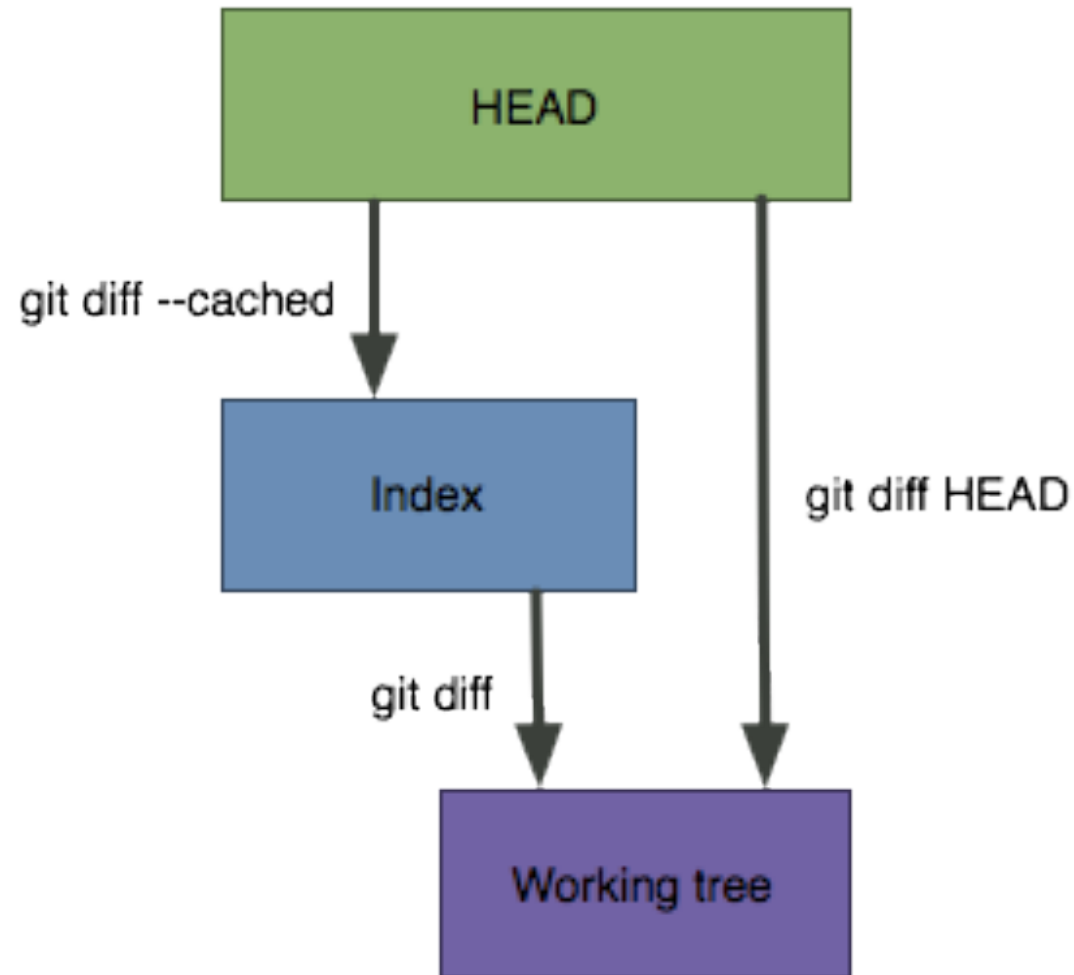

- To unstage a file, but retain your changes in the working tree:
  - ▣ `git reset HEAD <filename>`
- To discard current changes in the working tree, and make it look like the last commit:
  - ▣ `git checkout -- <filename>`
  - ▣ **Be careful! You will lose your changes and not get them back!**

# Removing a file

---

- ❑ To remove a file from the working tree and in the next commit, simply **git rm <filename>**
- ❑ To remove it from the next commit, but keep the file in the working tree, do **git rm --cached <filename>**

# Viewing diffs of files

# Viewing diffs of files

```
cliu:git charlesliu$ git diff HEAD
diff --git a/d b/d
index 2d9d466..8163fc1 100644
--- a/d
+++ b/d
@@ -1,5 +1,5 @@
  blah blah blah this is version 1
-blah blah blah this is line 2 of version 1
+this is line 2 of version 1
  this is line 3
-and 4
  6.470 is awesome
+added new line here
```

# The .gitignore file

---

- ❑ Specifies files that you don't want Git to track under version control
- ❑ Commonly used for compiled files, binaries, large asset files (e.g. images)
- ❑ Can use wildcards (e.g. \*.pyc, \*.png, Images/\*, etc.)
- ❑ Be careful – if you add a file to .gitignore after it's already been tracked, potential issues
- ❑ A list of recommended .gitignore files:  
<https://github.com/github/gitignore>

## Use case #2: branching

- ❑ What is a branch?
- ❑ Branching commands
- ❑ The HEAD pointer
- ❑ Basics of merging
- ❑ Basics of rebasing
- ❑ Aside: the git reset command

# What is a branch?

- ❑ Visualize a project's development as a “linked list” of commits.
- ❑ When a development track splits, a new branch is created.
- ❑ In Git, branches are actually just a pointer to these commits

# Branching commands

---

- ❑ List all branches in the project – **git branch**
- ❑ Create a new branch – **git branch <branchname>**
- ❑ Switch to a branch – **git checkout <branchname>**
- ❑ Create and immediately switch – **git checkout -b <branchname>**
- ❑ Delete a branch – **git branch -d <branchname>**

# Stashing

---

- Working tree must be clean when switching branches
- Stash changes that you don't want to commit at that time – **git stash**
  - ▣ Puts a stash onto the stack
- Later, apply the most recent stashed changes and remove that stash – **git stash pop**

# The HEAD pointer

- Recall: all branches simply a pointer to a commit
- HEAD: special pointer to the current branch, moves around as you switch branches

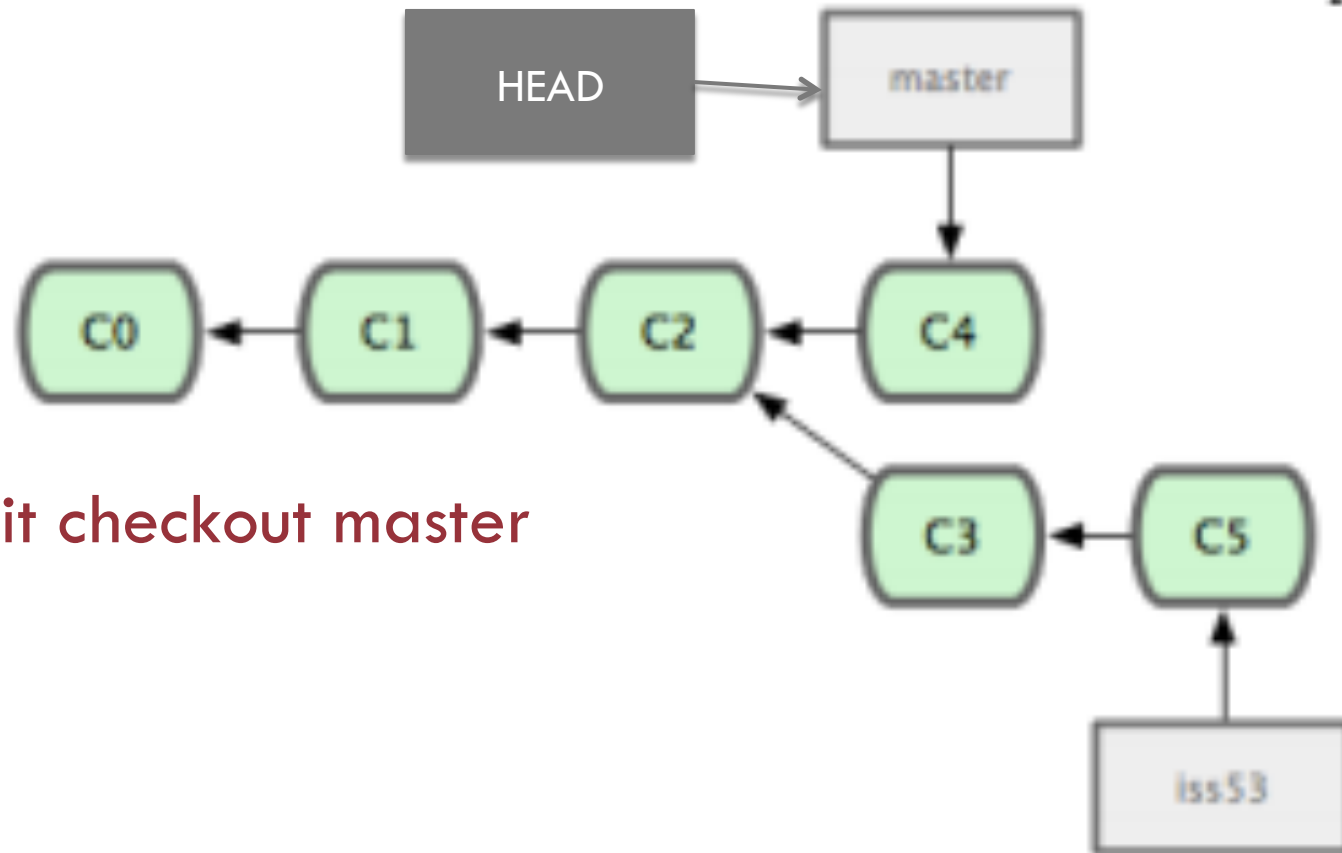

# Merging

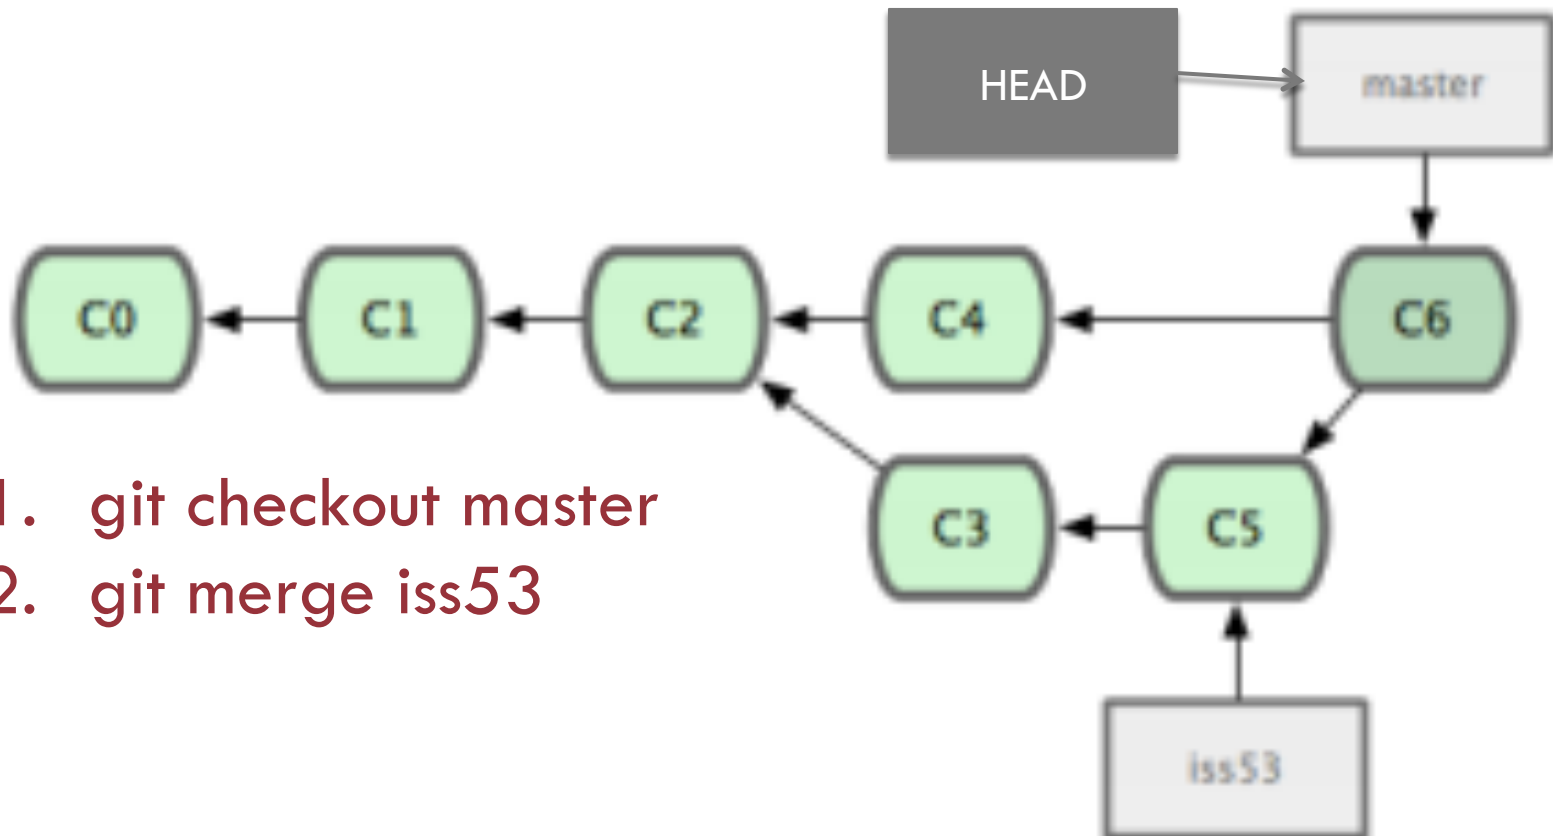

# Merging

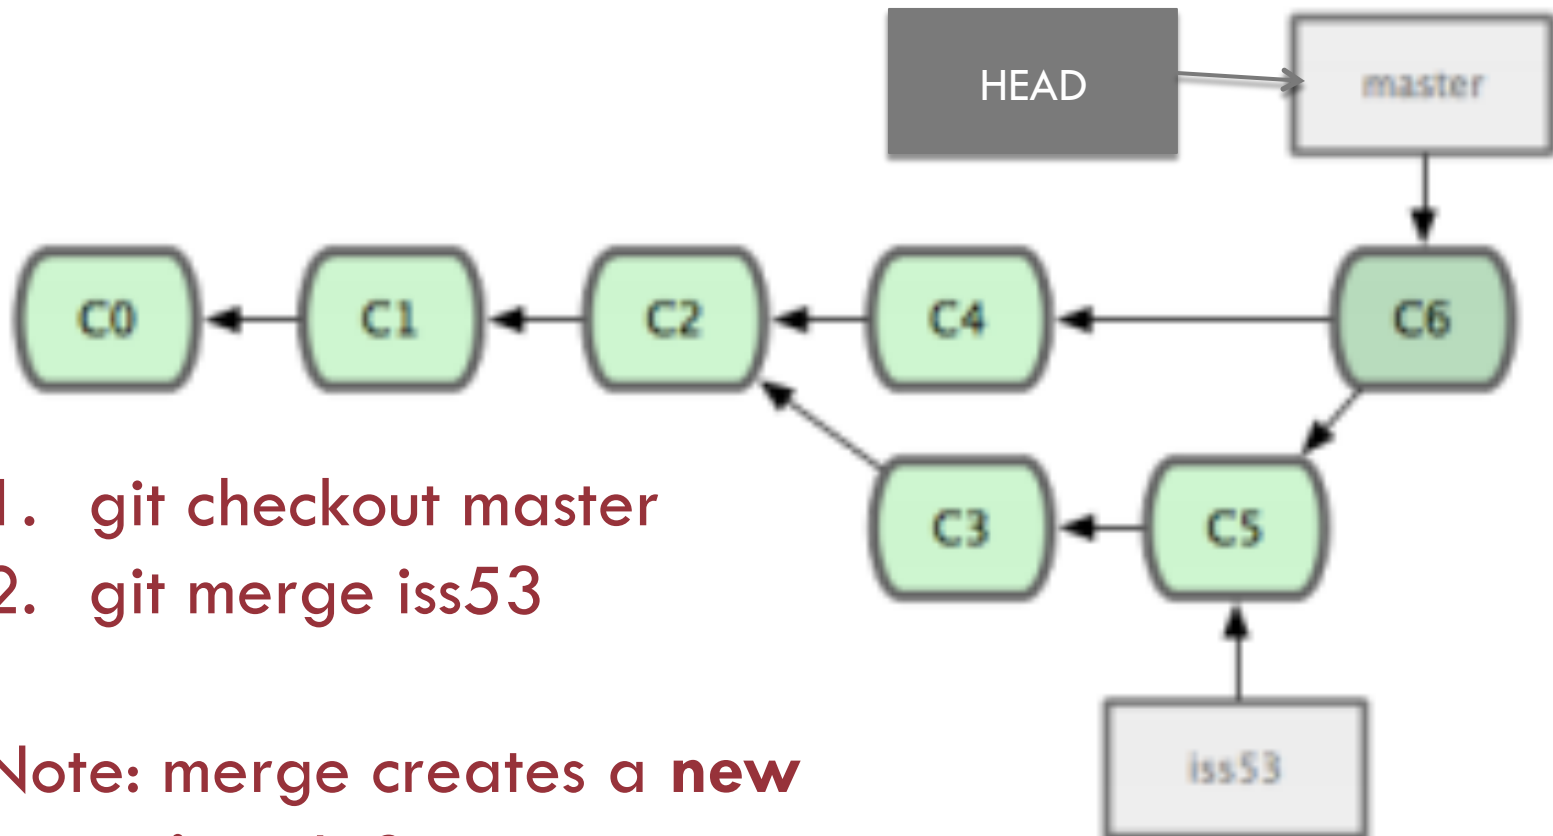

1. git checkout master

# Merging

1. git checkout master
2. git merge iss53

# Merging

1. git checkout master
2. git merge iss53

Note: merge creates a **new commit** with 2 parents!

# Merge commits

Before merge...master and new have diverged  
(commit 3 on master vs. commit 1 on new branch)

```
[~/example]$ git branch Picture Shape Media Arrange
* master
new
[~/example]$ git log
commit 04a5abc1ee028687ceebf5addaf7bcedd478b68c
Author: Charles Liu <cliu2014@mit.edu>
Date: Tue Jan 7 02:39:35 2014 -0500
    commit 3 on master

Date: Tue Jan 7 02:37:43 2014 -0500

    commit 1 on master
[~/example]$
```

**Old tip of master**

**Old tip of new branch**

# Merge conflicts

- Sometimes, two branches will edit the same piece of code in different ways.
- Must resolve the conflict manually, then add the conflicting files and explicitly commit.

```
[~/example]$ git merge new
Auto-merging file1
CONFLICT (content): Merge conflict in file1
Automatic merge failed; fix conflicts and then commit the result.
```

```
1 file1      : Text
2 edit2
3 edit3 1 1 1 1 1 0 1 1
4 <<<<<< HEAD
5 edit4
6 =====
7 conflicting edit
8 >>>>>> new
```

Conflict markers

# Merge conflicts

```
[~/example]$ git status
# On branch master
# Unmerged paths:
#   (use "git add/rm <file>..." as appropriate to mark resolution)
#
#       both modified:   file1
#
```

```
commit 3830f43d17358b1307a8cf6aee40361c5d060be1 Arranged to merge
Merge: 6fdf49d 6929a70
Author: Charles Liu <cliu2014@mit.edu>
Date: Tue Jan 7 02:49:53 2014 -0500

    Merge branch 'new'

Conflicts:
    file1
```

# Rebasing

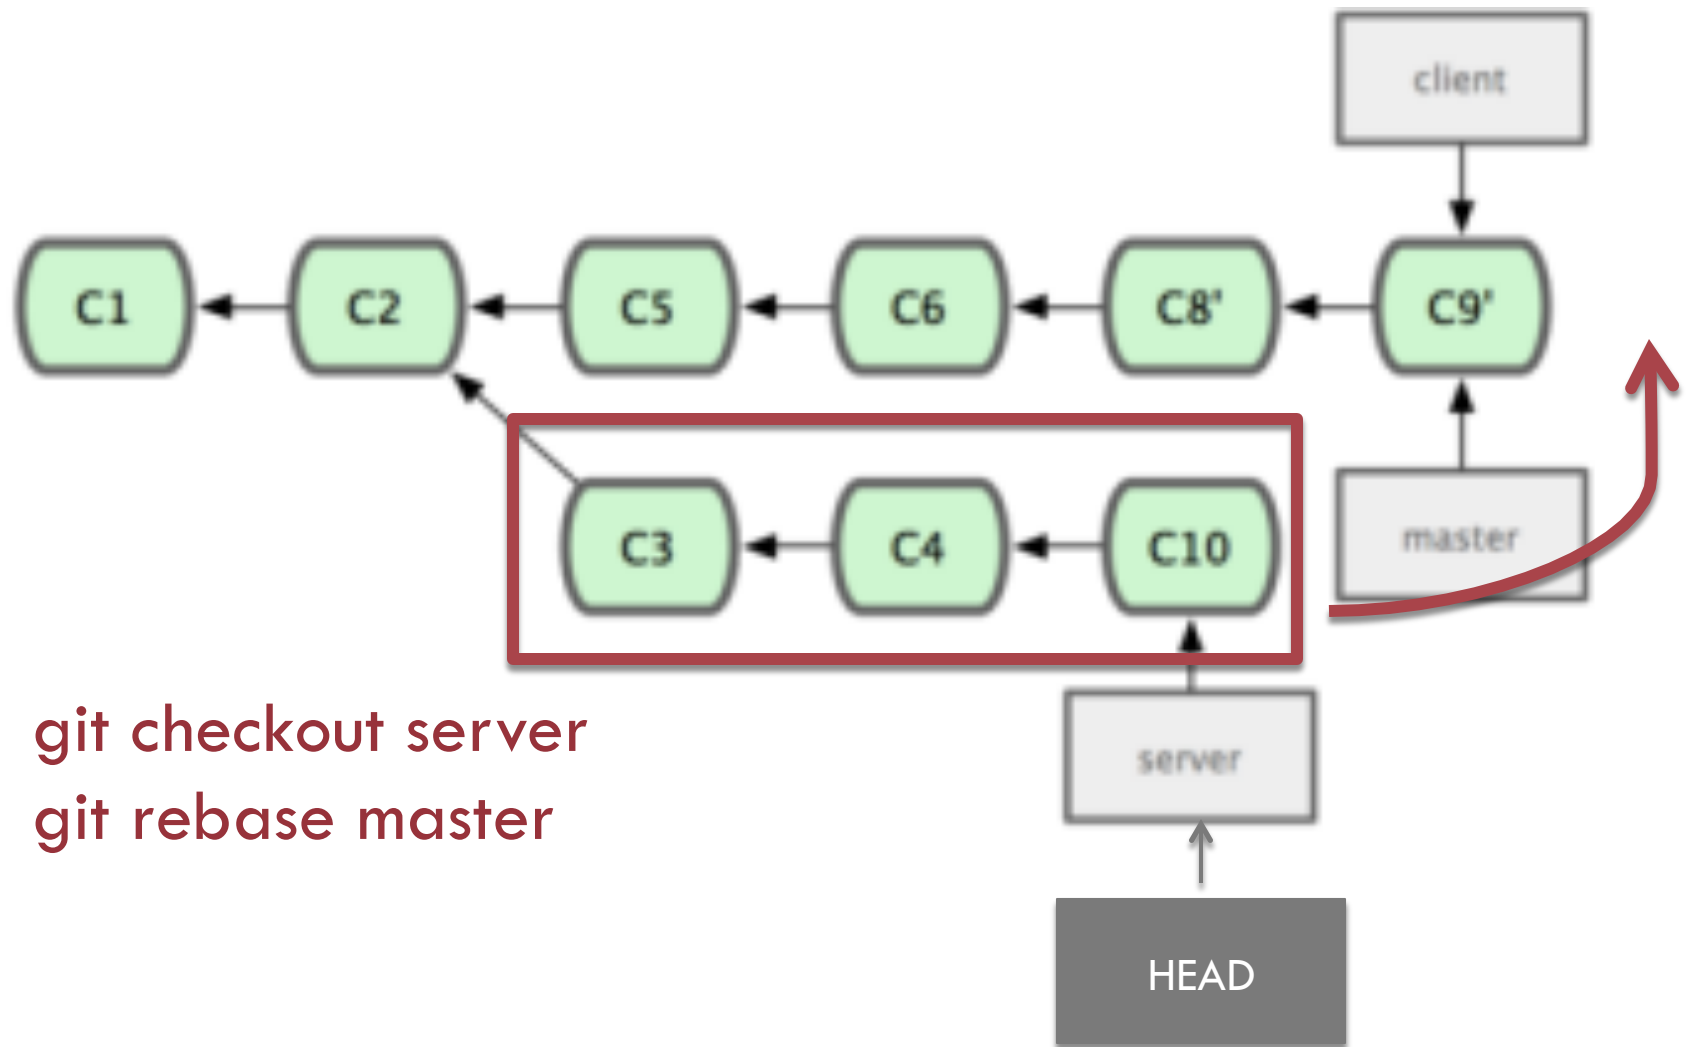

- Instead of a merge, which creates a **new commit** originating from both branches, a **rebase** takes the contents of one branch after the “split” and moves them to the end of the other branch.
- The command **git rebase <basebranch>** takes your currently checked out branch and **replays the diffs** on top of basebranch.

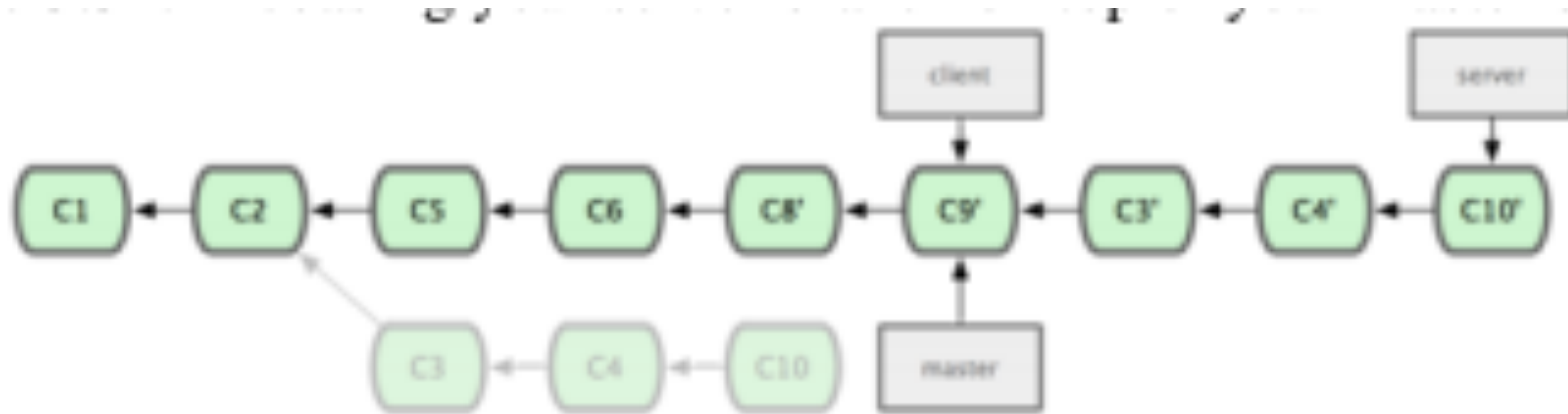

# Rebasing

# Rebasing

# Rebasing

1. git checkout server
2. git rebase master

# Why rebase?

- Creates a linear history; often cleaner and easier to read.
- But...**DO. NOT. EVER.** rebase anything that has already been pushed to a repo someone else has access to
  - ▣ Rebasing removes commits and writes new ones; but someone else might have already based their work off your old commits!

# An aside...the git reset command

- 3 versions...and often the source of much confusion!
  - ▣ `git reset --soft <commit / pointer to commit>`
  - ▣ `git reset --mixed <commit / pointer to commit>` (or simply `git reset`)
  - ▣ `git reset --hard <commit / pointer to commit>`
- Reset proceeds in 3 steps:
  1. Move the HEAD pointer
  2. Update the index/staging area to the new contents of HEAD
  3. Update the working directory

# 3 steps to reset

1. Move the HEAD pointer – soft stops here.
2. Update the index/staging area to the new contents of HEAD – mixed stops here.
3. Update the working directory – hard stops here

**Note: reset --hard overwrites the working directory. This is another command that can potentially cause loss of data!**

## Use case #3: collaboration

- ❑ Creating a repo on Github
- ❑ Remotes
- ❑ Remote-tracking branches
- ❑ Push, fetch, and pull
- ❑ The git clone command

# Remotes

---

- A target computer that has Git repos that you can access
  - ▣ Via http(s), ssh, or git protocols
- **git remote add <remotename> <remoteaddress>**
- **git remote -v (view remotes)**
- **git remote rm <remotename>**
- Often, with one remote, we name it “origin”

# Authenticating to Github

- Sometimes recommends HTTPS, but often SSH easier
- Need to generate a keypair:  
<https://help.github.com/articles/generating-ssh-keys>

# Github – SSH keys

---

- `cd ~/.ssh; ls`
- If a file named `id_dsa.pub` or `id_rsa.pub` does not exist:
  - `ssh-keygen -t dsa -C "<your email here>"`
  - `ssh-add id_dsa`
- `pbcopy < ~/.ssh/id_dsa.pub` (on Macs)

# Github – SSH keys

1. Click “account settings”

The screenshot shows the GitHub Enterprise interface for user cliu2014. The top navigation bar includes the 'github:enterprise' logo, a search bar, and links for 'Explore', 'Gist', and 'Help'. The user's profile icon and name 'cliu2014' are on the right. A red box highlights the 'Account Settings' icon (a gear) in the top right.

On the left sidebar, the 'SSH Keys' link is highlighted with a red box. Other links include Profile, Account Settings, Emails, Notification Center, Security History, Applications, Repositories, and Organizations.

The main content area shows the 'SSH Keys' section. A red box highlights the 'Add SSH key' button. Below it, a table lists existing keys, with one key named 'mbp' and its fingerprint. A 'Delete' button is next to it. A red box also highlights the 'Delete' button.

Below the table is the 'Add an SSH Key' form. It has a 'Title' field and a large 'Key' text area. A red box highlights the 'Key' text area with the text '4. Paste your key here'. At the bottom of the form is a green 'Add key' button.

Annotations on the image include:

- 1. Click “account settings” (pointing to the top right gear icon)
- 2. Click “SSH Keys” (pointing to the sidebar link)
- 3. Click “Add SSH key” (pointing to the top right button in the SSH Keys section)
- 4. Paste your key here (pointing to the large text area for the key)

# Create a repo

**Quick setup** — if you've done this kind of thing before

Repo URL

 **Setup in Mac**

or

HTTP

SSH

git@github.mit.edu:cliu2014/6470\_demo.git

We recommend that every repository has a **README**, **LICENSE**, and **.gitignore**

## Create a new repository on the command line

```
touch README.md
git init
git add README.md
git commit -m "first commit"
git remote add origin git@github.mit.edu:cliu2014/6470_demo.git
git push -u origin master
```

## Push an existing repository from the command line

```
git remote add origin git@github.mit.edu:cliu2014/6470_demo.git
git push -u origin master
```

# Pushing and fetching

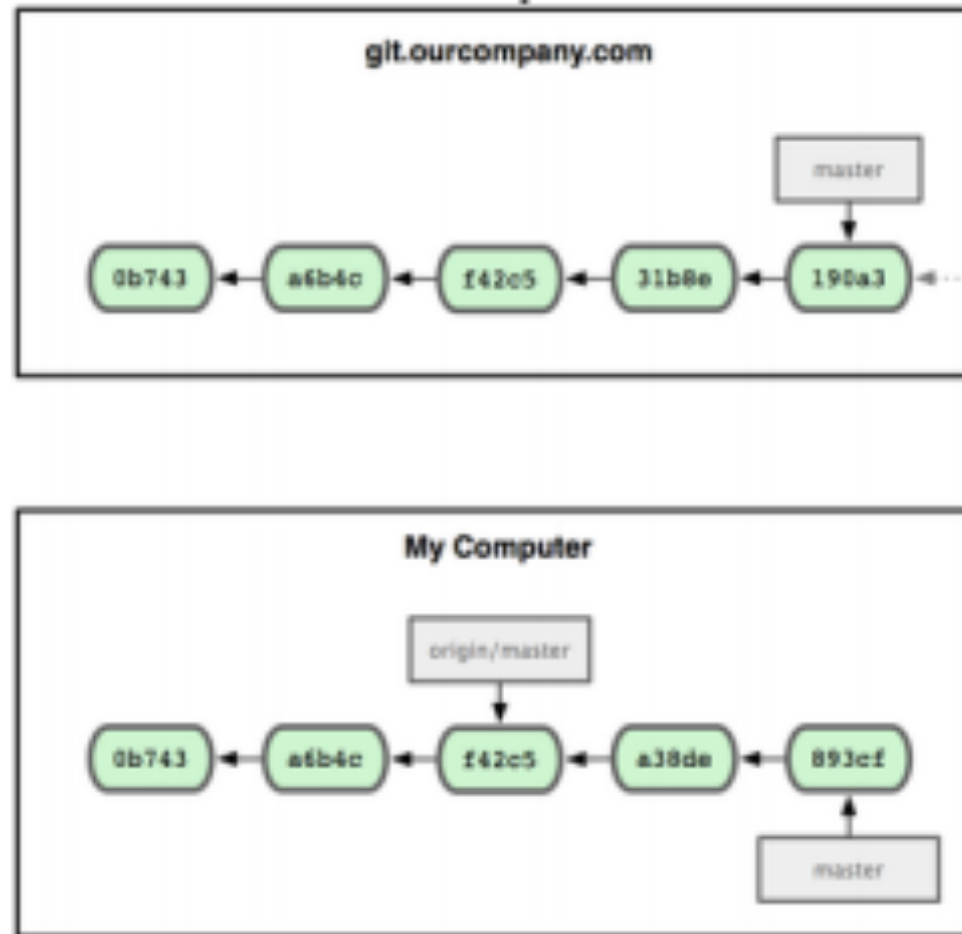

- **git push <remotename> <branchname>** sends your code in the branch up to the remote
  - ▣ Often just git push: depends on settings but often equivalent to git push origin master
- **git fetch <remotename>**

# Remote tracking branches

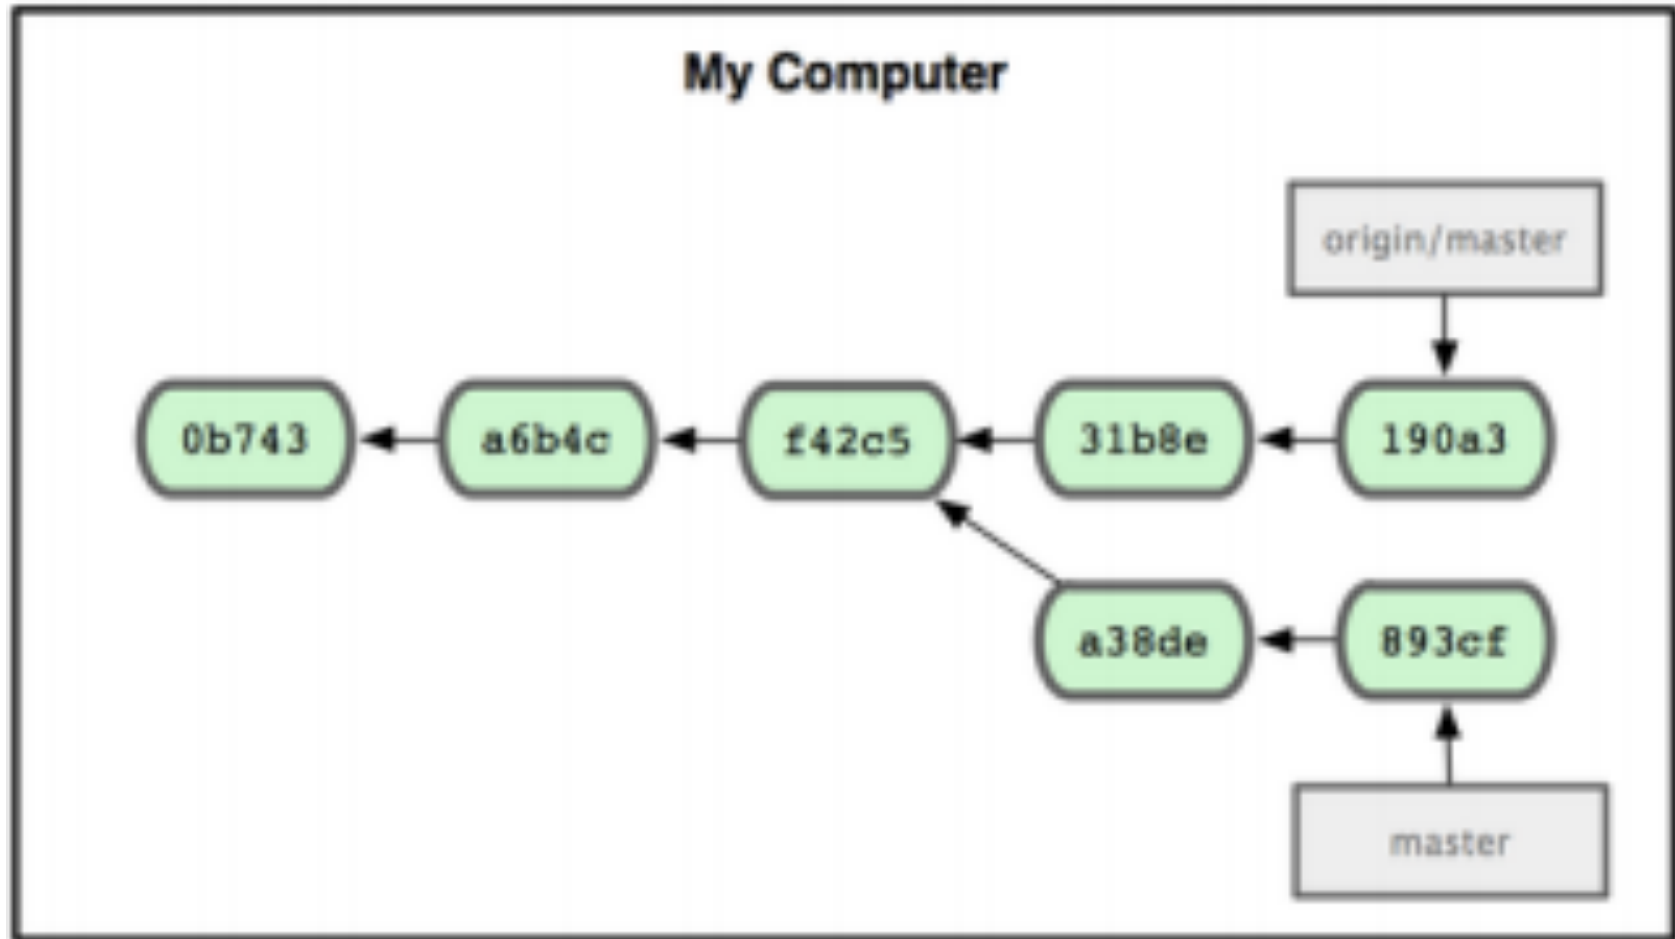

- When you do git fetch, you don't immediately see the changes. Why?
- Changes are fetched to a “**remote tracking branch**”
  - ▣ Branches associated with a remote, but treat them like a local branch
  - ▣ Can merge with your current master (git checkout master; git merge origin/master)
  - ▣ Even better...rebase

# Remote tracking branches

# Remote tracking branches

## In summary...

- ❑ **Basic workflow in git**
  - ❑ Adding, committing, viewing diffs
- ❑ **Branches**
  - ❑ The HEAD pointer, merging, and rebasing
- ❑ **Remotes**
  - ❑ Pushing and fetching; quick introduction to Github

# Lots of other topics

- ❑ Tags and version numbers
- ❑ Interactive rebase: squashing and amending commits
- ❑ Relative pointers from HEAD (e.g. HEAD^^, HEAD~3)
- ❑ Submodules
- ❑ Using your own server as a git server (bare repos)
- ❑ Git as a filesystem (git grep, git ls-files, etc.)
- ❑ GUIs to view trees and graphical merge tools
- ❑ ...more!

# For more information

---

- The book *Pro Git* (which I based much of this presentation on), available for free!
  - ▣ <https://github.s3.amazonaws.com/media/progit.en.pdf>
  - ▣ Covered Chapters 1-3 in detail, very simple ideas from Chapters 4-6
- Git documentation: do **git help <commandname>**
- Google, StackOverflow, etc.

# That's all for today!

- We're done with client-side technologies!
- Office hours tonight, 7-9pm in 32-044 (basement of Stata)
- Tomorrow: 11am in 26-152 (8.01 teal room)
  - Introduction to server-side technologies, SQL databases, UI/UX
